Recent Trends in Type 2 Diabetes Mellitus-Related Inpatient Care $RTI(h)(S)_{M}$ **Among Pediatric Patients in the United States**

BACKGROUND

- Type 2 diabetes mellitus (T2DM), the most common form of diabetes (> 90% of all cases), is typically associated with adult obesity
- Recently, increasing attention has been given to the growing prevalence of disease among pediatric populations
- Among the pediatric population, obesity is the most important predictor for the development of T2DM^{1,2}
- A previous study assessing the incidence of T2DM and its association with obesity among a pediatric population (aged < 20 years) reported a 10-fold increase in the incidence of T2DM during a 12-year period, with all patients being classified as obese (mean body mass index: 37.7) at T2DM diagnosis³
- However, there are limited data assessing recent trends in T2DM-related hospitalizations among the pediatric population $(age \le 20 years)$

OBJECTIVE

• To assess trends in pediatric T2DM hospitalization and aspects of related care in the United States (US)

METHODS

Study Design

Retrospective database analysis

Data Source

- Discharge data were taken from the 2000, 2003, 2006, and 2009 Healthcare Cost and Utilization Project (HCUP) Kids' Inpatient Database (KID)
- Largest all-payer pediatric inpatient care database in the US
- Only national pediatric hospital database with charge information on all patients, regardless of payer
- Includes many clinical and nonclinical variables for each inpatient stay, including patient demographics, diagnosis codes, length of stay (LOS), total charges, admission and discharge status, payer, and hospital-specific characteristics
- Sampling weights allow for generating nationally representative estimates

Inclusion Criteria

- Age \leq 20 years
- Primary diagnosis of T2DM (International Classification of Diseases, Ninth Revision, Clinical Modification [ICD-9-CM] codes 250.x0, 250.x2)
- Unique patient identifiers were not provided, so we were unable to follow patients who moved from facility to facility

Study Measures and Analytical Method

- For each of the four years the following information was gathered for T2DM-related hospitalizations:
- Weighted estimates of the number of hospitalizations – Characteristics
- Per-discharge total charges and LOS
- Most frequently observed secondary diagnoses
- Results were compared with hospitalizations unrelated to T2DM
- Analyses were carried out using SAS (Version 9.3) statistical software

RESULTS

Incidence and Patient Characteristics (Table 1)

- Discharges related to T2DM in the US (weighted):
- 1,636 in 2000 (2.0/100,000 US pediatric population in 2010)
- 2,201 in 2003 (2.7/100,000 US pediatric population in 2010)
- 3,004 in 2006 (3.5/100,000 US pediatric population in 2010)
- 2,320 in 2009 (2.7/100,000 US pediatric population in 2010)
- Female patients accounted for a greater percentage of T2DM-related discharges than male patients in 2000, 2003, and 2006; in 2009, the percentages between the sexes were nearly equal
- In all study years, more than 64% of patients with T2DM-related hospitalizations were aged 16 to 20 years
- Nearly 70% of hospitalizations unrelated toT2DM were among patients aged younger than 5 years
- Black patients accounted for 25.4% to 31.2% of T2DM-related hospitalizations and 10.9% to 13.4% of hospitalizations unrelated to T2DM
- The proportion of discharges unrelated to T2DM was the greatest in the southern region of the US
- In 2000 and 2003, private insurance was the largest payer of T2DM-related hospitalizations, but in 2006 and 2009, the Medicaid system paid for a greater proportion of T2DM-related hospitalizations

Admission Source and Discharge Disposition (Table 2)

- A substantially greater proportion of T2DM-related hospitalizations originated in the emergency department (62.3%-72.2%) compared with hospitalizations unrelated to T2DM (17.4% to 19.7%)
- Approximately 94% of discharges unrelated to T2DM and 90% of discharges related to T2DM were routine discharges
- The death rate in T2DM-related stays ranged from 2.5% to 5.0% across the years; the death rate in stays unrelated to T2DM was generally less and ranged from 2.8% to 3.2%

Table 1. Characteristics of T2DM-Related Hospitalizations^{a,b}

Table 2. Admission Source and Discharge Disposition of T2DM-Related Hospitalizations^{a,b}

^b Counts were weighted to obtain nationally representative estimates

Total Charges and LOS (Figures 1 and 2)

- Mean total charges (2012 US dollars) for T2DM-related discharges increased nearly 34%, from \$13,775 (2000) to \$18,432 (2009)
- The mean total charge per discharge for hospitalizations unrelated to T2DM also increased over time, eventually nearly equaling the mean total charge forT2DM-related hospitalizations (from \$12,262 in 2000 to \$18,563 in 2009)

Most Frequently Observed Secondary Diagnoses During T2DM-Related Hospitalizations

- In each of the study years, the most frequently observed secondary diagnosis was for diabetic ketoacidosis (either ICD-9-CM diagnosis code 250.10 or 250.12)
- In each of the study years, "Personal history of noncompliance with medical treatment, presenting hazards to health" (ICD-9-CM diagnosis code V15.81) was in the top-five most frequently observed secondary diagnoses
- In 2006 and 2009, "Long-term (current) use of insulin" (ICD-9-CM diagnosis code V58.67) was the second most frequently observed secondary diagnosis code, indicating that a significant proportion of these patients are treated, at least in part, with insulin

LIMITATIONS

- Patient discharges were identified based upon diagnosis codes that, if recorded inaccurately, may cause misidentification of T2DM
- Because unique patient identifiers were not provided, we were unable to assess how many distinct patients were represented by the admissions in the database, or to follow patients who moved from facility to facility or had a readmission
- Results may be biased somewhat if the experiences of patients who transferred from facility to facility differed from those who remained in the same facility, or if readmissions differed from initial admissions

CONTACT INFORMATION

Sean D Candrilli, PhD Head, Health Economics Phone: +1.412.384.2790 Fax: +1.919.541.7222

- Mean LOS for T2DM-related hospitalizations fell slightly during the study period, from 3.2 days in 2000 to 2.9 days in 2009
- In comparison, the mean LOS for discharges unrelated to T2DM was slightly greater and increased modestly over time, from 3.5 days in 2000 to 3.7 days in 2009

Figure 2. Mean LOS, by Year, Among Those With and Without T2DM

CONCLUSIONS

- We observed significant increases in the rate of pediatricT2DM-related hospitalization over time, with tremendous growth in the economic burden associated with these stays (i.e., nearly a 150% increase in total charges between 2000 and 2006)
- Total pediatricT2DM-related inpatient charges increased from \$21.5 million (2012 US dollars) to \$53.3 million, before falling slightly in 2009 to \$42.4 million
- The increasing hospitalization rates are consistent with the growing prevalence of obesity among children in the US
- These findings further emphasize the need for interventions targeted at mitigating and managing factors associated with the risk of T2DM (e.g., obesity) among children
